Grampian University Hospitals

Blood results on admission showed deranged LFTs with albumin 32, total bilirubin 32, AAT 161, alkphos 132 and GGT 769. Amylase was also elevated at 151 and he had a CRP of 25. In the haematology results MCV and MCH were raised at 107 and 36 respectively, platelets were reduced at 103. Chest x-ray on admission was clear. In view of the deranged LFTs, Mr Laing was sent for an abdominal ultrasound scan. Apart from a simple cyst in the upper pole of the right kidney, the ultrasound scan report failed to reveal any abnormalities. In particular there was no evidence of any metastatic disease in the liver and there was no dilatation of the bile ducts. However, gallstones were not noted in the gallbladder.

During the time of admission his LFTs began to improve and the symptoms began to recede. In view of the above it was decided that the blood results and they symptoms had been due to gallstones disease which had now passed away. It is advisable therefore that this gentleman is referred on an outpatient basis to the General Surgeons for later cholecystectomy. There is no follow up arranged by this department. However, if there are any further questions please do not hesitate to get in touch.

With kind regards

Yours sincerely

Imali M Fernando, SHO
